The initial release of CUTE, a widely used testing environment for optimization software, was described in [2]. A new version, now known as CUTEr is presented. Features include reorganisation of the environment to allow simultaneous multi-platform installation, new tools for, and interfaces to, optimization packages, and a considerably simplified and entirely automated installation procedure for UNIX systems. The environment is fully backward compatible with its predecessor, offers support for Fortran 90/95 and a general C/C++ Application Programming Interface. The SIF decoder, formerly a part of CUTE, has become a separate tool, easily callable by various packages. It features simple extensions to the SIF test problem format and the generation of files suited to automatic differentiation packages.

Additional Key Words and Phrases: Nonlinearly-constrained optimization, testing environment, shared filesystems, heterogeneous environment, SIF format

1. INTRODUCTION

The CUTE testing environment for optimization software and the associated test problem collection originated from the need to perform extensive and documented testing on the LANCELOT package [10]. Because the large set of test problems and testing facilities produced in this context were useful in their own right, they were extended to provide easy interfaces with other commonly used optimization packages, gathered in a coherent multi-platform framework and made available, on the world wide web and via anonymous ftp, to the research community. The paper [2] provides an overview of the environment, and full documentation of the available tools and interfaces at the time.

Since 1993, the CUTE environment and test problems have been widely used by the community of optimization software developers [1; 3; 4; 7; 8; 11; 12; 13; 14; 15; 22; 24; 26; 27; 28; 32; 33; 37; 38; 39; 40; 42; 43; 44]. Such widespread use has inevitably led to a clearer awareness of the deficiencies of the original design, and also created a demand for new tools and new interfaces. The environment has evolved over time by the addition of new test problems and minor updates to a number of tools. The present paper aims to describe its next major evolution: CUTEr, in which we revisit the original CUTE design. This new release is characterized by

—a set of new tools, including a unified facility to report the performance of the various optimization packages being tested,

—full backward compatibility with CUTE,

—a set of new interfaces to additional optimization packages,

—some Fortran 90/95 support, and

—an integrated C/C++ Application Programming Interface.

The SIF optimization test-problem decoder, which used to be a constituent part of the CUTE environment, has been isolated into a separate package named SifDec. Any software that could require the decoding of a SIF file may now rely on it, as a package in its own right. It is characterized by

—the definition and support of an extension to SIF (the Standard Input Format) allowing for easier input of quadratic programs and for casting the problem against a selection of parameters, such as the problem size, and

—the ability to generate input files suited to automatic differentiation tools, such as the HSL [30] `AD01` and `AD02` packages [36].

Both CUTEr and SifDec have the following features:

—Completely new organization of the various files that make up the environment, now allowing concurrent installations on a single machine and shared installations on a network, and

—a new simplified and automated installation procedure, but

—the restriction of the environment to UNIX systems.

The last of these items is the reason why the rest of the paper only considers directory structures and/or file names in a style typically found on UNIX systems. To some, the restriction to UNIX systems might seem a retrograde step because

CUTE offered VMS and some DOS support, but this merely reflects our current expertise.

This paper is intended to supersede the parts of [2] that are deprecated in CUTEr, to complement it in order to cover the new features and to describe the new SifDec environment. It is organized as follows. Section 2 discusses the new organization of the CUTEr environment files. Section 3 documents the new tools and discusses application program interfaces. Section 4 documents the new interfaces to additional optimization packages and Section 5 covers the isolated SIF decoder environment, the extension of the SIF description language to quadratic programs, and its support of user-changeable parameters. Section 6 describes the new installation procedures. Details of how the packages may be obtained are given in Section 7, and concluding comments are presented in Section 8.

2. A NEW FLEXIBLE ORGANIZATION

One of the defects of CUTE is that it was not designed to support a multi-platform environment; that is, instances of the environment that could be used simultaneously from a central server on several, possibly different, machines, with their own dialects of UNIX. Moreover, using CUTE on a single machine in conjunction with several different compilers (a case that frequently occurs when new software is tested) is extremely cumbersome. Likewise, handling different instances of the environment corresponding to different *sizes* of the tools (that is the size of the test problems that they can handle) is problematic. The reason for these difficulties is that the structure of the CUTE files, as described in [2], does not lend itself to such use, because it only contains a single subtree of objects files. If we call the combination of a machine, operating system, compiler and size of the tools an *architecture*, the obvious solution to such a defect is then to allow several such subtrees in the installation, one for each architecture.

However, as soon as the possibility of using architecture-dependent subtrees is raised, the proper identification of the parts (scripts, programs) of the environment that are independent of the architecture also becomes an issue. Since it would be inefficient to store copies of these independent scripts and programs in each subtree, it is natural to store them in a data structure that is itself disjoint from the dependent subtrees. Finally, the propagation of subtrees containing sometimes very similar yet vitally different data makes the maintenance of the environment substantially more complicated, and therefore requires enhanced tools and a clear distinction between the parts of the environment that are related to testing optimization software and those related to its own maintenance.

The directory organization chosen for CUTEr, shown in Fig. 1, reflects these considerations. We now briefly describe its components.

Starting from the top of the figure, the first subtree under the main `$CUTER` directory (the root of the CUTEr environment) is `build`, which essentially contains all the files necessary for installation and maintenance. Its `arch` subdirectory contains the files defining all possible architectures that are currently supported by CUTEr, allowing users to install new architecture-dependent subtrees as they are required, depending on the testing needs and the evolution of platforms, systems and compilers. The `prototypes` subdirectory contains the parts of the environment that have to be specialized to one architecture before they can be used. We call such files

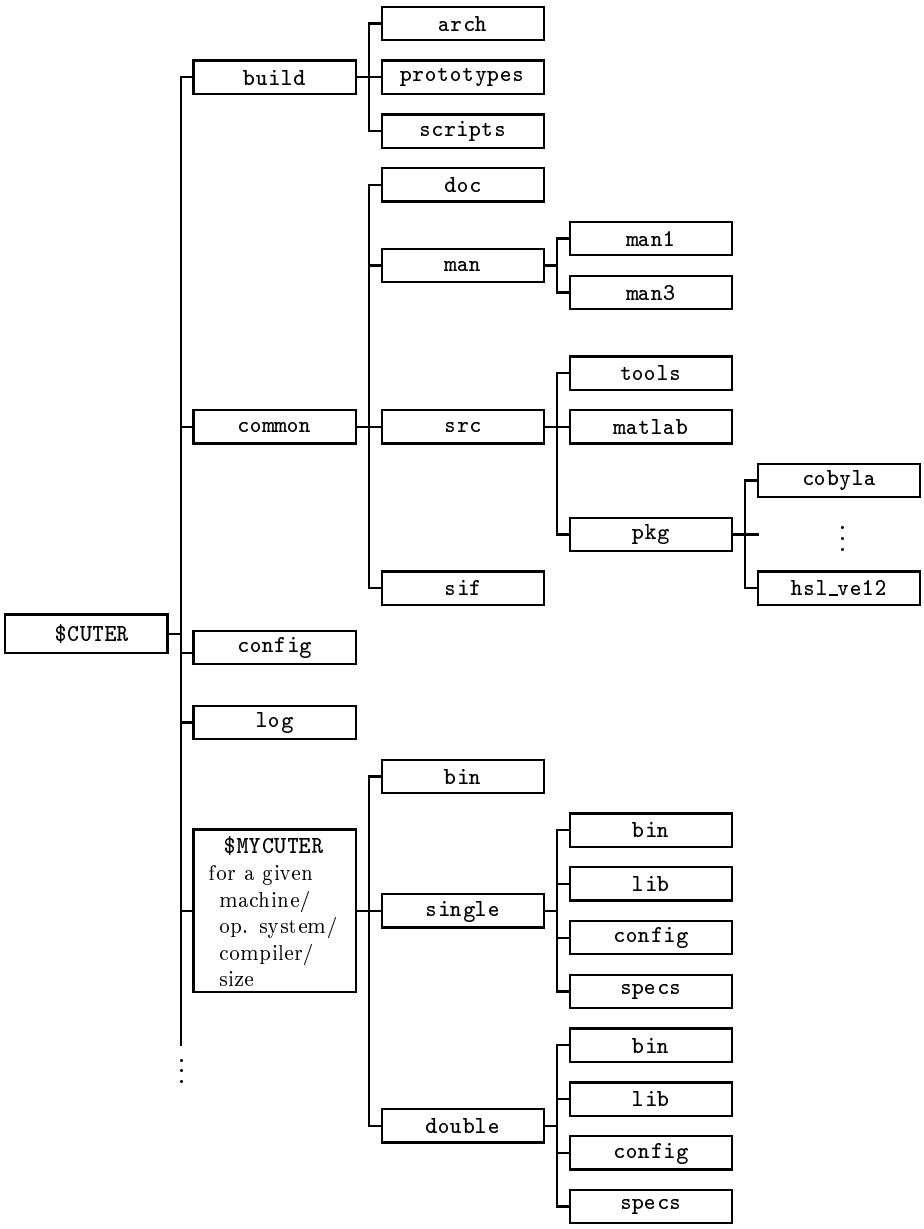

Fig. 1. Structure of the CUTEr directories

prototypes and the process of specializing them to a specific architecture *casting*. The prototype files include a number of tools and scripts whose final form typically depends on compiler options and the chosen size of the tools. Finally, the remaining subdirectory of `build`, named `scripts`, contains the environment maintenance tools and various documentation files.

The second subtree under `$CUTER` is called `common` and contains the environment data files that are relevant for the purpose of testing optimization packages, but are independent of the architecture. Subdirectory `doc` contains a number of documentation files concerning the environment, such as a description of its structure and procedures to follow for interfacing the supported optimization packages. The CUTEr tools and scripts themselves are documented in the `man` subdirectory, and, as is common on UNIX systems, its `man1` and `man3` subdirectories. The `src` subdirectory contains the source files for many of the environment utilities disseminated in a number of subdirectories. We briefly describe them in turn. `tools` contains the sources of the Fortran tools used in user's programs. `matlab` contains all the "m-files" that provide a MATLAB interface to the environment. `pkg` holds information related to the various optimization packages for which CUTEr provides an interface—these being stored separately in their own subdirectory of `pkg`; Fig.1 represents those for COBYLA and `HSL_VE12`. Each of these package-specific subdirectories typically includes an algorithmic specification file and a suitable `README` description of how to build an interface between CUTEr and the package. The last subdirectory, `sif`, contains a few test problems in SIF format.

The next subdirectory under `$CUTER` is called `config` and contains all the configuration and rules files needed to generate the platform-specific *Makefiles*.

The `log` subdirectory of `$CUTER` contains a history of the various installations—and, possibly, subsequent un-installations—of the environment for the various architectures.

The remaining subdirectories of `$CUTER` are all architecture dependent: each corresponds to the installation of CUTEr in a specific machine, for a given operating system and compiler and for a given tool size. The figure only represents one, but the continuation dots at the bottom of the leftmost vertical line indicate that there might be more than one. Although these directories have been symbolically represented as subdirectories of `$CUTER` in the figure to reflect their dependence upon `$CUTER`, they may be located anywhere on the host system, including on remote machines over the local network. The names of these directories are (by default) automatically chosen at installation, but a user of one of these subtrees would typically give it a symbolic name, like `$MYCUTER`, to distinguish the version of CUTEr currently in use. Each architecture-dependent subtree is divided into its single precision and double precision instances (`single` and `double`, respectively), each of these containing four subdirectories. The first, `bin`, contains the object files corresponding to the driving programs for the optimization packages and, if relevant, for the package codes themselves. If applicable, it should also contain the Fortran 90/95 module information files, that is those usually suffixed by `.mod`. The second, `lib`, contains the library of CUTEr tools and, if relevant, any object libraries associated with the interfaced optimization packages. The `config` subdirectory contains the architecture-dependent files that were used to build the current `$MYCUTER` subtree (they are reused when a tool or optimization package is added or updated), while

`specs` contains the algorithmic specification files for the optimization packages that are architecture dependent, if any. Finally, `$MYCUTER/bin` contains scripts that are architecture, but not precision, -dependent.

The fact that the CUTEr tools are now stored in the form of libraries (while they were stored as a collection of individual object files in CUTE), is another new feature. This allows a much simpler design of new optimization package interfaces, because the interface no longer needs to specify the exact list of tools that need to be loaded with the package.

A final new feature of the environment organization is that the documentation is available via the usual `man` command for the scripts and tools, and in ASCII, postscript and pdf formats for the rest.

3. NEW FEATURES

This section describes innovations in CUTEr, from the point of view of optimization software and the manipulation of data decoded from problems. Section 3.1 describes recently added CUTEr tools which handle data to be used by optimization software while Section 3.2 concentrates on programming languages support.

3.1 New tools

The CUTEr tools for unconstrained and constrained optimization are presented in Tables 1 and 2 respectively, accompanied by a brief description. Storage of the Hessian matrix of either the objective or the Lagrangian function may be either dense or sparse. Unless otherwise specified, sparse storage occurs in coordinate format [17, §2.6]. Explicit mention is made whenever the storage scheme is instead finite-element format [17, §10.5]. Besides the general CUTEr documentation, man pages describing all supplied tools and their calling sequence are included in the distribution.

Users of the previous versions of CUTE will notice a number of new tools for both unconstrained—or bound-constrained—and constrained problems. We note the `uvarty` and `cvarty` tools, whose purpose is to determine the type of each variable, which may be continuous, binary (0-1) or integer. For constrained problems, the tool `cdimen` determines the number of variables and constraints involved. The tools `cdimse` and `cdimsh` determine the number of nonzero entries in the Hessian of the Lagrangian when using (respectively) finite-element or general sparse matrix storage, and thus allow users to set appropriate array sizes in advance, while `cdimsj` does the same for the constraint Jacobian. The tool `cscifg` is now obsolete and replaced by `ccifsg`. For backward-compatibility reasons, the former is included but simply calls the latter as a subroutine. Programs that ran under earlier versions of CUTE will therefore still run under CUTEr. Similarly, for unconstrained problems, the new tools `udimen`, `udimse` and `udimsh` determine the number of variables involved, and the numbers of nonzeros in the Hessian in finite-element and sparse formats respectively. Finally, the `ureprt` and `creprt` tools produce statistics about a particular run on (respectively) an unconstrained or constrained test problem, reporting data such as total CPU time, number of iterations, function and constraints evaluations (if appropriate), number of evaluations of their derivatives, and the number of Hessian matrix-vector products used.

All the external package drivers supply report data using the `ureprt` and `creprt`

Tool name	Brief description
ubandh	extract a banded matrix out of the Hessian matrix
udh	evaluate the Hessian matrix in dense format
udimen	get the number of variables involved
udimse	determine the number of nonzeros required to store the sparse Hessian matrix in finite-element format
udimsh	same as udimse, in sparse format
ueh	evaluate the sparse Hessian matrix in finite-element format
ufn	evaluate function value
ugr	evaluate gradient
ugrdh	evaluate the gradient and Hessian matrix in dense format
ugreh	evaluate the gradient and Hessian matrix in finite-element format
ugrsh	evaluate the gradient and Hessian matrix in sparse format
unames	obtain the names of the problem and its variables
uofg	evaluate function value and possibly gradient
uprod	form the matrix-vector product of a vector with the Hessian matrix
usetup	set up the data structures for unconstrained optimization
ush	evaluate the sparse Hessian matrix
uvarty	determine the type of each variable
ureprt	obtain statistics concerning function evaluation and CPU time used

Table 1. The unconstrained optimization CUTEr tools.

tools. These drivers have filenames matching the `*ma.f` or `*ma.f90` expression. They may be found in `$CUTER/common/src/tools` before compilation and under the name `$MYCUTER/`*precision*`/bin/*ma.o` after compilation. For example, the hypothetical source package `pak.f` needs to be compiled into `$MYCUTER/`*precision*`/bin/pak.o`. All the object files and the relevant libraries are subsequently linked by the corresponding interface, following the procedure described in Section 4.

3.2 New Application Programming Interfaces

In this section, we comment on the possibility of hooking optimization software written in Fortran 90/95 or C/C++ to CUTEr.

CUTEr makes provision for optimization or linear algebra codes written in standard Fortran 90/95 by providing explicit interface blocks to all tools present in the library and delayed compilation in case module information is not present at installation time. As guidelines to writing new Fortran 90/95 interfaces, a generic interface `gen90ma` and a real interface `ve12ma`, interfacing the HSL code HSL_VE12 are already part of the CUTEr distribution.

Optimization and linear algebra software increasingly use the flexibility and generality of object-oriented languages like C++ and, more generally, enjoy the benefits and portability of the C language. As a response to those interests, CUTEr provides a C/C++ Application Programming Interface to every tool available in the environment. This interface is transparent in the sense that users need not worry about architecture or compiler-dependent details as these are treated internally.

At the time of this writing, only the most popular combinations of Fortran and C compilers have been considered, but inevitably further support will be provided in the future.

Tool name	Brief description
ccfg	evaluate constraint functions values and possibly gradients
ccfsg	same as ccfg, in sparse format
ccifg	evaluate a single constraint function value and possibly gradient
ccifsg	same as ccifg, in sparse format
cdh	evaluate the Hessian of the Lagrangian in dense format
cdimen	get the number of variables and constraints involved
cdimse	determine number of nonzeros to store the Lagrangian Hessian in finite-element format
cdimsh	determine number of nonzeros to store the Lagrangian Hessian in coordinate format
cdimsj	determine number of nonzeros to store the matrix of gradients of the objective function and constraints, in sparse format
ceh	evaluate the sparse Lagrangian Hessian in finite-element format
cfn	evaluate function and constraints values
cgr	evaluate constraints gradients and objective/Lagrangian gradient
cgrdh	same as cgr, plus Lagrangian Hessian in dense format
cidh	evaluate the Hessian of a problem function
cish	same as cidh, in sparse format
cnames	obtain the names of the problem and its variables
cofg	evaluate function value and possibly gradient
cprod	form the matrix-vector product of a vector with the Lagrangian Hessian
cscfg	evaluate constraint functions values and possibly gradients in sparse format
cscifg	same as cscfg, for a single constraint
csetup	set up the data structures for constrained optimization
csgr	evaluate constraints and objective/Lagrangian function gradients
csgreh	evaluate both the constraint gradients, the Lagrangian Hessian in finite-element format and the gradient of the objective/Lagrangian in sparse format
csgrsh	same as csgreh, in sparse format instead of finite-element format
csh	evaluate the Hessian of the Lagrangian, in sparse format
cvarty	determine the type of each variable
creprt	obtain statistics concerning function evaluation and CPU time used

Table 2. The constrained optimization CUTEr tools.

4. NEW INTERFACES

CUTEr contains a number of additional interfaces to existing packages (as well as interfaces to newer versions of previously supported packages) beyond those offered with CUTE. The purpose of providing these interfaces is to allow researchers to run a variety of solvers on a consistent set of test examples, and thus to assess the respective merits of each for solving classes of related problems, and practitioners to solve simplified versions of their problems or similar problems by established solvers and cross-compare the results. The newly supported packages are:

filterSQP. This nonlinear programming package combines filter and trust-region methods to globalize an SQP iteration [21; 22; 23]. The filterSQP package is maintained by, and may be obtained from, Roger Fletcher (`fletcher@maths.dundee.ac.uk`) and Sven Leyffer (`leyffer@mcs.anl.gov`).

HRB. To convert matrices (for example, Hessians, Jacobians, and KKT augmented system matrices) derived from SIF problem data into Harwell-Boeing [18; 19] or Rutherford-Boeing [20] sparse matrix formats. HRB was written by Nick

Gould, and is unique in CUTEr in that the interface requires no external package.

HSL_VE12. This package finds critical points of nonconvex quadratic programming problems using an interior-point trust-region algorithm [9]. `HSL_VE12` is part of HSL [30] and was written by Nick Gould and Philippe Toint.

KNITRO. This minimizes a smooth nonlinear function subject to nonlinear equality and inequality constraints using an interior-point approach. The resulting barrier subproblems are treated using SQP. KNITRO [6] is maintained by Jorge Nocedal (`nocedal@ece.northwestern.edu`) and Richard Waltz (`rwaltz@ece.northwestern.edu`).

L-BFGS-B. This package [45] treats unconstrained or bound constrained problems. It uses a limited memory BFGS quasi-Newton method and is available from Jorge Nocedal (`nocedal@ece.northwestern.edu`).

LOQO. A linesearch-based primal-dual interior-point code for nonlinear programming, using an SQP approach and direct factorizations [41]. LOQO is maintained by its author Robert Vanderbei (`rvdb@princeton.edu`).

PRAXIS. This is Brent's algorithm, reimplemented in Fortran 77 by John Chandler, for unconstrained minimization without derivatives [5]. It is available from John Chandler (`jpc@a.cs.okstate.edu`).

SNOPT. This package [25] minimizes a smooth linear or nonlinear function subject to bounds and sparse linear or nonlinear constraints using sequential quadratic programming (SQP). The package may be obtained from Philip Gill (`pgill@ucsd.edu`).

The implementation of the interfaces differ slightly from that of past CUTE releases. If *pak* is a generic name for an interface, the scripts `sdpak` and `pak` are found under `$MYCUTER/bin`. The script `sdpak` applies the SIF decoder (see Section 5) to an input problem, sets a number of environment variables, collects and compiles source and object files as necessary, links them together and executes the resulting program. The script `pak` is similar to `sdpak` except it assumes the input problem has already been decoded.

Generic interfacing scripts—`sdgen` and `gen` for Fortran 77 packages and `sdgen90` and `gen90` for Fortran 90/95 packages—may also be found in `$MYCUTER/bin`. These serve the purpose of helping users to design interfaces to new or currently unsupported packages. The corresponding prototype files may be found under the directory `$CUTER/build/prototypes`.

Besides the general CUTEr documentation, man pages describing all supplied interfaces are included in the distribution. Documentation for installing and using the package *pak* may be found in the directory `$CUTER/common/src/pkg/`*pak*. Note, however, that the supported packages are *not* supplied in CUTEr, rather directions on how to obtain them are indicated on the official CUTEr website (see Section 7). Object files should be placed where CUTEr can find and link them—for instance in `$MYCUTER/`*precision*`/bin`, where *precision* is the working precision. The precision-independent specification files for the package *pak* are found in the directory `$CUTER/common/src/pkg/`*pak*, whereas if the options specification files depend on the working precision, they are found in `$MYCUTER/`*precision*`/specs`.

5. AN ISOLATED SIF DECODER

In this section, we examine the new design of the SIF decoder. In contrast with earlier versions of CUTE [2], the SIF decoder is not embedded in CUTEr. We believe that this may be justified for a number of reasons. Firstly, while the decoder is used intensively by the CUTEr testing environment, there is no *a priori* reason why it should not also be useful in other contexts. As a prime example, the SIF decoder plays a vital role in the package LANCELOT B (an updated version of the LANCELOT package [10]) from the GALAHAD [29] optimization software library. It is thus more consistent to isolate the decoder and simply have any dependent packages call it as needed. Another reason for our decision is ease of maintenance, and consistency when upgrading the decoder—all the packages that refer to it are then guaranteed to use the same version. Finally, the SIF decoder may evolve in its own right and develop separately. For example, it has recently been extended to generate routines for function evaluation suited for input to the HSL automatic differentiation packages `HSL_AD01` and its threadsafe counterpart `HSL_AD02` [30]. The resulting isolated decoder has been named SifDec.

5.1 A new design

The design and contents of the SifDec directory tree are very similar to the new design of CUTEr described in section 2 and reflects similar concerns. The design is summarized in Fig. 2. Corresponding environment variables play corresponding roles; the root of the tree is called `$SIFDEC` while the current instance of SifDec is referred to as `$MYSIFDEC`. In addition, the `doc` subdirectory contains the complete SIF reference document.

5.2 Extensions to the SIF

5.2.1 *Quadratic programs.* A long source of irritation for CUTE users was that the SIF representation of test problems did not explicitly allow for quadratic objective functions (although it was obviously possible to represent such functions via suitable nonlinear element functions). Since this situation arises frequently, and as a number of extensions to the MPS Linear Programming format from which SIF evolved are in use [31; 34; 35], we have chosen to extend the original SIF format to handle quadratic parts of the objective function in a more flexible manner. We now briefly describe this extension for the reader already familiar with the SIF format as specified in [10]. The terminology we used is adopted from there.

In [10], the objective function is represented as a *group partially separable function* consisting of several potentially nonlinear *groups*. The purpose of our extension is to allow one of the groups to be specified as a quadratic objective group, whose type of nonlinearity is immediately identified by its definition without the need for additional nonlinear group or element functions. More precisely, the objective function is now assumed to have the form

$$f(x) = \sum_{i \in I_O} g_i(\xi_i) + \tfrac{1}{2} \sum_{j=1}^{n} \sum_{k=1}^{n} h_{j,k} x_j x_k, \quad \text{with} \quad \xi_i = \sum_{j \in J_i} w_{i,j} f_j(\bar{x}_j) + a_i^T x - b_i,$$

where $x = (x_1, x_2, \ldots, x_n)$. The term $\frac{1}{2} \sum_{j=1}^{n} \sum_{k=1}^{n} h_{j,k} x_j x_k$ in the objective function is the *quadratic objective group* and constitutes an extension to the format

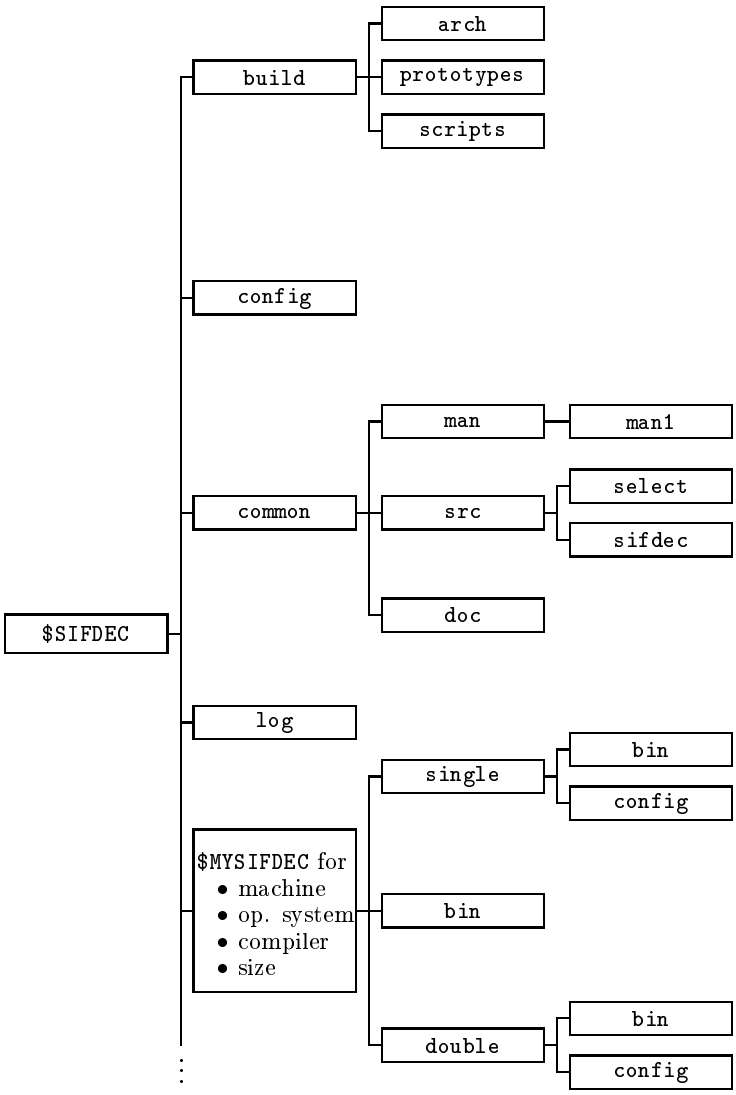

Fig. 2. Structure of the SifDec directories

proposed in [10]; the leading $\frac{1}{2}$ is present by convention. This decomposition is illustrated in Example 5.1.

Example 5.1: In order to fix the ideas, let us consider the optimization problem

$$\text{minimize } f(x_1, x_2) = e^{x_1^2} + x_2^2 + 4x_1x_2.$$

Its objective function then comprises two groups, the first of which ($e^{x_1^2}$) uses a non-trivial nonlinear group function $g(\alpha) = e^\alpha$. The rest of the objective function may then be considered as a quadratic objective group and written as

$$\tfrac{1}{2}(h_{1,1}x_1x_1 + h_{1,2}x_1x_2 + h_{2,1}x_2x_1 + h_{2,2}x_2x_2),$$

where $h_{1,1} = 0$, $h_{1,2} = h_{2,1} = 4$ and $h_{2,2} = 2$. □

The quadratic objective group is specified in the SIF file by a new section starting with the keyword (or indicator *card*) `QUADRATIC` (the cards `HESSIAN`, `QUADS`[1], `QUADOBJ`[2] and `QSECTION`[3] are treated as synonyms of `QUADRATIC`); this section must appear between the sections `START POINT` and `ELEMENT TYPE` (see [10, §7.2.1]).

Within this new section, each line is used to specify at most two values of $h_{i,j}$ that share a common value of i or j; any $h_{i,j}$ not recorded is assumed to have the value zero, only one of the pair $(h_{i,j}, h_{j,i}), i \neq j$, should be given, and any repeated values will be summed. The syntax for data following these indicator cards is given in Table 3.

F.1	Field 2	Field 3	Field 4		Field 5	Field 6
3	←10→	←10→	← 12 →		←10→	← 12 →
`QUADRATIC` *or*						
`HESSIAN` *or*						
`QUADS` *or*						
`QUADOBJ` *or*						
`QSECTION`						
	var name	*var name*	*num value*		*var name*	*num value*
`X`	*var name*	*var name*	*num value*		*var name*	*num value*
`Z`	*var name*	*var name*			*arr name*	
2	5	15	25	36	40	50 61

Table 3. Possible data cards for `QUADRATIC`, `HESSIAN`, `QUADS`, `QUADOBJ` or `QSECTION`

The strings *var name* in data fields 2 and 3 (and optionally 2 and 5 for those cards whose field 1 does not contain `Z`) give the names of pairs of problem variables x_j and x_k for which $h_{j,k}$ is nonzero. All problem variables must have been previously set in the `VARIABLES/COLUMNS` section. Additionally, on a `Z` card, the name of the variable must be an element of an array of variables, with a valid name and index, while on a `X` card, the name may be either a scalar or an array name.

[1] For compatibility with Ponceleón's proposal [35].
[2] For compatibility with Maros and Meszaros' test set [34].
[3] For compatibility with OSL [31].

On cards whose field 1 is either empty or contains the character `X`, the strings *num value* in data fields 4 and (optionally) 6 contain the associated numerical values of the coefficients $h_{j,k}$. On cards for which field 1 contains the character `Z`, the string *arr name* in data field 5 gives a real parameter array name. This name must have been previously defined and its associated value then gives the numerical value of the parameter.

In Example 5.1, if the variables x_1 and x_2 are named `X1` and `X2`, the `QUADRATIC` section for this problem takes the form given in Table 4.

F.1	Field 2	Field 3	Field 4	Field 5	Field 6
3	10	10	12	10	12
QUADRATIC					
	X2	X1	4.0	X2	2.0

Table 4. The SIF file specification for Example 5.1

This extension to the SIF format has resulted in our including the Maros and Meszaros collection of quadratic programming test problems [34] as an annex to the main CUTEr collection. The complete test set may be downloaded from the location `http://cuter.rl.ac.uk/cuter-www/mastsif.html`.

5.2.2 *User-changeable parameters.* One of the less convenient features of SIF-encoded problems was that the decoding procedures in CUTE were not designed to recognise, nor alter, instance-dependent variable parameters such as problem dimensions or critical coefficients. Many real models, particularly those arising from some form of discretization, depend upon parameters that a user might wish to refine. With CUTE, a user wishing to change such a parameter was forced to edit the SIF file. This file was usually provided with a number of suggested values, all but one of which were "commented out". To remove this inconvenience, SifDec makes provisions for both the definition and the altering of variable parameters from the problem-decoding scripts.

Any real or integer parameter definition containing the comment `$-PARAMETER` in field 5 (i.e., in columns 40-49) defines that parameter to be a *variable* parameter. This is consistent with old-style SIF-encoded problems because strings starting with `$` in this field were previously treated as comments. Any characters after `$-PARAMETER` are regarded as comments, and will be passed back to a user on request. All SIF files in the CUTE collection that previously contained variable parameters have been updated to take advantage of this new SifDec facility, but of course they are still consistent with CUTE.

Given this extra syntax, the SIF decoding scripts have been extended to support two new options, allowing users to select variable parameters in the SIF file. The first of these options, `-show`, prints all the variable parameters present in the SIF file, along with suggested values to which they may be set as well as any other provided comments. The second, `-param` allows users to choose, from the command line, which values to assign to these parameters. For instance, assuming that `N` and `THETA` have been marked as variables parameters of `SAMPLE.SIF` and that `N=400` and `THETA=3.5` are valid values, the command

```
sifdecode -param N=400,THETA=3.5 SAMPLE.SIF
```

(see Section 4 for a discussion of the related script `sdpak`, which also inherits these features) will decode `SAMPLE.SIF` into the appropriate subroutines and data files, setting `N` to 400 and `THETA` to 3.5.

These new features allow users to solve systematically a set of problems in all prescribed sizes. Default values are given in each SIF file, and we have taken the opportunity to raise these defaults to reflect the size of problems that we feel ought to be of current interest, given that many of the previous defaults were assigned over ten years ago and are rather small to challenge state-of-the art solvers.

As an extension of the `-param` command-line option, users may force a problem to be solved using parameter values that may not have been pre-assigned in the SIF file. This is done using the `-force` option, as in

```
sifdecode -force -param N=1000,THETA=3.5 SAMPLE.SIF
```

where `SAMPLE.SIF` might not contain the parameter setting `N=1000`, or `THETA=3.5`. Omitting the `-force` option would result in an abort of the process, while specifying it results in the SIF decoder and the optimizer attempting to complete the solve using the specified values. Since nothing guarantees that these values are valid, the `-force` command-line option should be used carefully.

6. THE NEW INSTALLATION PROCEDURES

We now describe the CUTEr installation procedure. It applies equally to SifDec, the only difference being the names of the procedures invoked, as we mention at the end of this section.

The installation of CUTEr is driven by portability concerns and is performed by the script `install_cuter`, which prompts for information on the local architecture and environment and the desired compiler, creates the appropriate directory structure but leaves the local installation to *Umakefiles*. *Umakefiles* can be considered as *Makefile* generators, or "meta *Makefiles*" in that they generate *Makefiles* suited to the local platform and architecture without user intervention. Their use is fully documented within CUTEr and they are in fact a simplified flavour of *Imakefiles* [16]. They greatly ease the task of the user when it comes to modifying the size of the CUTEr tools and rebuilding part of their instance of CUTEr, as *Makefiles* rebuild only what needs to be rebuilt. The *Umakefiles* needed to build a complete instance of CUTEr rely on a set of configuration files stored under `$MYCUTER/config`, where the details about the local architecture are contained. Should users need to modify local parameters, they can do so by editing two files, namely `Umake.tmpl` and the configuration file corresponding to their platform; for instance `sun.cf`, `linux.cf`, `ibm.cf`, etc. The *Makefiles* then need to be re-generated and CUTEr needs to be rebuilt using normal `make` commands.

The installation script searches the `$CUTER/build/arch/f.arch` file to present a list of possible Fortran compilers to the user. This does not imply that the corresponding compilers are actually installed on the local system but this list is meant to represent the most common compilers on that system. Details about each compiler in the list are found in the file `$CUTER/config/`*platform*`.cf` if it is platform-specific or in `$CUTER/config/all.cf` if it is available on all platforms. Similarly, the file `$CUTER/build/arch/c.arch` is searched for possible C/C++ compilers. Addition of a compiler, can normally be achieved by modifying one "similar" to those provided. The files `$CUTER/config/`*platform*`.cf` and `$CUTER/config/all.cf` should be checked

before the installation procedure is initiated.

The configuration files also provide basic system commands and definition of a temporary directory. Some or all of these files may need to be properly modified, although suitable settings are given for systems we have access to.

During installation, the option to choose between small, medium, large or custom "sizes" for CUTEr is provided. These sizes come pre-specified, but may be tuned by editing the `size.*` files in the directory `$CUTER/build/arch` and re-issuing the install command.

The installation procedure works by casting *prototype files* against the system, compiler, precision and size information chosen by the user, casting the Fortran source files following the same pattern, and compiling and possibly linking the result. Each installation is logged, both for information purposes and with subsequent un-installation possibilities in mind. Un-installing an installed CUTEr is carried out by the script `uninstall_cuter`, which also updates the log file. The CUTEr tools, documentation, scripts, or other may be updated by the script `update_cuter`, as updates and bug fixes become available.

The installation procedure for SifDec is identical, with the sole proviso that the names `install_script_cuter`, `install_cuter`, `update_cuter`, `uninstall_cuter`, `CUTER` and `MYCUTER` should instead be interpreted as `install_script_sifdec`, `install_sifdec`, `update_sifdec`, `uninstall_sifdec`, `SIFDEC`, and `MYSIFDEC` respectively.

7. OBTAINING CUTEr AND SifDec

CUTEr and SifDec are written is standard ISO Fortran 77, but additionally CUTEr provides support for Fortran 90/95 and C/C++ packages. Single and double precision versions are available in a variety of sizes. Machine dependencies are carefully isolated and easily adaptable, making installation on heterogeneous networks possible. Automatic installation procedures are available for a variety of Unices, including LINUX. CUTEr and SifDec can be downloaded from

`http://cuter.rl.ac.uk/cuter-www`, and
`http://cuter.rl.ac.uk/cuter-www/sifdec`

respectively. Information on updates as well as indications on how to obtain the supported optimization and linear algebra software is available on the websites.

8. CONCLUSION AND PERSPECTIVES

This paper describes improvements and new features of CUTEr, the latest release of the CUTE testing environment, and of SifDec, the isolated SIF decoder. The purposes of CUTEr are to

—provide a way to explore an extensive collection of problems,

—provide a way to compare existing packages,

—provide a way to use a large test problem collection with new packages,

—provide motivation for building a meaningful set of new interesting test problems,

—provide ways to manage and update the system efficiently, and

—do all the above on a variety of popular platforms.

SifDec has been isolated and designed in order to

—supply a consistent interface to any package that may require the decoder, such as CUTEr and LANCELOT-B [10],

—ease its maintenance, upgrading and addition of new capabilities,

—provide access to automatic differentiation packages.

The environments are currently only available for UNIX platforms, but it is possible to install both packages on shared-filesystem local networks, because machine dependencies have been carefully isolated. A number of previously unsupported optimization and linear algebra packages are now interfaced to CUTEr, and corresponding driver programs are supplied. New tools for both constrained and unconstrained optimization have been added. Some support for automatic differentiation packages is now integrated into SifDec. Documentation now appears in different forms, including the usual UNIX manual pages describing the tools and interfaces, postscript and pdf general documentation covering installation, maintenance and usage. Additional details will be provided on the dedicated websites. It is hoped that installing CUTEr and SifDec on currently unsupported UNIX platforms, as well as writing interfaces for additional optimization packages, will be found relatively easy.

In the future, we plan to merge the different CUTEr tools so as to remove their dependency on whether the input problem is constrained or not, and have a single consistent set of tools. We also intend to use automatic memory allocation to remove the dependency of both the SIF decoder and the CUTEr tools on preselected sizes. An intuitive graphical user interface (GUI) is under way to ease the installation phase, to manage the different local installations of CUTEr and SifDec, and to enable the user to work in a unified environment. As already mentioned, the websites will keep up-to-date information about new features for both packages, bug fixes, new documentation and more.

Acknowledgments

Thanks to the following people for providing interfaces: Philip Gill for SNOPT, Jorge Nocedal and Richard Waltz for KNITRO, Sven Leyffer and Roger Fletcher for filterSQP. We also wish to thank CUTE users for their comments, bug reports, use, abuse and contributions. Finally detailed comments by Michael Saunders and an anonymous referee have been most useful.

APPENDIX

A. CALLING SEQUENCES FOR THE NEW EVALUATION TOOLS

In this section, we give the argument lists for those subroutines summarized in Tables 1 and 2 that are new to CUTEr; the remaining subroutines are fully documented in the appendix to [2]. There are two sets of tools: one set for unconstrained and bound constrained problems, and one set for generally constrained problems. Note that these two sets of tools cannot be mixed.

The superscript i on an argument means that the argument must be set on input. A superscript o means that the argument is set by the subroutine.

A.1 Unconstrained and bound constrained problems

—Discover how many variables are involved in the problem:

CALL UDIMEN (INPUT^i, N^o)

—Determine how many nonzeros are required to store the Hessian matrix of the objective function (when stored in a sparse format):
CALL UDIMSH (NNZH^o)

—Determine how many nonzeros are required to store the Hessian matrix of the objective function (when stored as a sparse matrix in finite-element format):
CALL UDIMSE(NE^o, NZH^o, NZIRNH^o)

—Obtain the type of each variable:
CALL UVARTY(N^i, IVARTY^o)

—Obtain statistics concerning function evaluation and CPU time use:
CALL UREPRT (UCALLS^o, TIME^o)

A.2 Generally constrained problems

—Discover how many variables and constraints are involved in the problem:
CALL CDIMEN (INPUT^i, N^o, M^o)

—Determine how many nonzeros are required to store the matrix of gradients of the objective function and constraints (when stored in a sparse format):
CALL CDIMSJ (NNZJ^o)

—Determine how many nonzeros are required to store the Hessian matrix of the Lagrangian (when stored in a sparse format):
CALL CDIMSH (NNZH^o)

—Determine how many nonzeros are required to store the Hessian matrix of the Lagrangian (when stored as a sparse matrix in finite-element format):
CALL CDIMSE(NE^o, NZH^o, NZIRNH^o)

—Obtain the type of each variable:
CALL CVARTY(N^i, IVARTY^o)

—Evaluate an individual constraint function and possibly its gradient (when this is stored in a sparse format):
CALL CCIFSG (N^i, I^i, X^i,CI^o, NNZSGC^o, LSGCI^i,SGCI^o, IVSGCI^o, GRAD^i)

—Obtain statistics concerning function evaluation and CPU time use:
CALL CREPRT (CCALLS^o, TIME^o)

A.3 Argument descriptions

The arguments in the above calling sequences have the following meanings:

CCALLS	is an array whose components give counts for various activities during the current execution of the constrained tools. Components are:
	CCALLS(1) number of objective function evaluations
	CCALLS(2) number of objective gradient evaluations
	CCALLS(3) number of objective Hessian evaluations
	CCALLS(4) number of Hessian-vector products
	CCALLS(5) number of constraint evaluations
	CCALLS(6) number of constraint Jacobian evaluations
	CCALLS(7) number of constraint Hessian evaluations
CI	is the value of the general constraint function I evaluated at X.

`GRAD` is a logical variable which should be set `.TRUE.` if the gradient of the constraint function is required from `CCIFSG`. Otherwise, it should be set `.FALSE.`

`I` is the index of the general constraint function to be evaluated by `CCIFSG`.

`INPUT` is the unit number for the decoded data, i.e., from which `OUTSDIF.d` (see [2]) is read.

`IVARTY` is an array whose i-th component indicates the type of variable i. Possible values are 0 (a variable whose value may be any real number), 1 (an integer variable that can only take the values zero or one) and 2 (a variable that can only take integer values).

`IVSGCI` is an array whose i-th component is the index of the variable with respect to which `SGCI`(i) is the derivative.

`LSGCI` is the declared dimension of `SGCI`.

`M` is the number of general constraints.

`N` is the number of variables for the problem.

`NE` is the number of elements in a finite-element representation of the Hessian for the problem.

`NZH` is the dimension of the array needed to store the real values of the finite-element Hessian.

`NZIRNH` is the dimension of the array needed to store the integer values of the finite-element Hessian.

`NNZH` is the number of nonzeros in the Hessian.

`NNZJ` is the number of nonzeros in the constraint Jacobian.

`NNZSGC` is the number of nonzeros in `SGCI`.

`SGCI` is an array that gives the values of the nonzeros of the gradient of the general constraint function `I` evaluated at `X`. The i-th entry of `SGCI` gives the value of the derivative with respect to variable `IVSGCI`(i) of function `I`.

`TIME` is an array whose components give CPU times (in seconds) for various activities during the current execution of the tools. Components are:

- `TIME(1)` CPU time for call to `USETUP/CSETUP.`
- `TIME(2)` CPU time since last call to `USETUP/CSETUP.`

`UCALLS` is an array whose components give counts for various activities during the current execution of the unconstrained tools. Components are:

- `UCALLS(1)` number of objective function evaluations
- `UCALLS(2)` number of objective gradient evaluations
- `UCALLS(3)` number of objective Hessian evaluations
- `UCALLS(4)` number of Hessian-vector products

`X` is an array that gives the current estimate of the solution of the problem.
